**CORRELATING AGRICULTURAL USE WITH AMBIENT AIR  
CONCENTRATIONS OF METHYL ISOTHIOCYANATE DURING THE  
PERIOD OF 2011 – 2014**

Christopher Collins

March 29, 2016

**Abstract**

In February 2011, as part of the Department of Pesticide Regulation's (DPR) mandate for continuous evaluation of currently registered pesticides, DPR implemented an Air Monitoring Network (AMN) for measuring pesticides in three agricultural communities. The AMN monitors for 32 pesticides, including methyl isothiocyanate (MITC), on a weekly basis. In this report, we explored the relationship between AMN-measured ambient MITC concentrations and reported use in each of the three AMN sampling locations during the period of 2011-2014. The spatial distribution of MITC-producing pesticide applications and local meteorological parameters were analyzed as part of this work.

Results showed that all three AMN sites possess unique detection-use profiles. Data showed that ambient MITC concentrations were not statistically correlated to the weekly use applied within 5 miles of the AMN sampling sites. Furthermore, detections of MITC during weeks without any reported use, particularly in Salinas and Shafter, could indicate that some number of detections may have occurred from MITC applications made further than 5 miles from the sampling sites. The data also suggests that methods of fumigant application which are designed to mitigate off-site movement of MITC and local weather at the time of application may have influenced the quantity of positive MITC detections.

## **1 Introduction**

Methyl isothiocyanate (MITC), a highly volatile compound with broad, non-selective biocidal activity, results from the breakdown of the dithiocarbamate salts metam sodium or metam potassium in the environment, particularly when in the presence of water (US EPA 2008; Merriman and Hebert 2007). An alternative source of MITC results from the breakdown of dazomet, a pesticide belonging to the thiadiazine class of chemicals (DPR 2002). Dazomet, metam potassium and metam sodium were first registered as pesticides in the United States (US) in 1967, 1973 and 1975, respectively, and were subsequently reregistered with the US Environmental Protection Agency (EPA) in 2008 to ensure the compounds meet current health and safety standards (US EPA 2008).

The dithiocarbamate salts and dazomet can be applied to various media (soils, sewers, wood products, etc.) to generate the primary volatile toxic degradate MITC which shows fungicidal, herbicidal, insecticidal, and nematicidal activity (US EPA 2008; Tomlin 2000). Combined, these compounds are some of the most widely applied pesticides in California, with nearly 12 million pounds of MITC applied during 2014 alone (DPR 2015a).

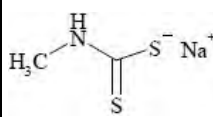

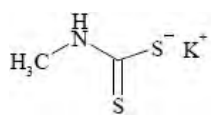

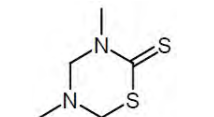

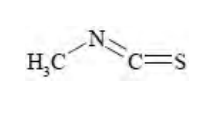

In February 2011, as part of the Department of Pesticide Regulation's (DPR) mandate for continuous evaluation of currently registered pesticides, DPR implemented an Air Monitoring Network (AMN) for measuring pesticides in three agricultural communities. In this report, we characterize the relationship between ambient concentrations of MITC with reported use in each of the three AMN communities monitored during the period of February 1, 2011 – December 31, 2014. The local wind patterns and spatial distribution of MITC-producing pesticide applications are also presented.

## **2 Background**

### **2.1 Chemical Description**

MITC precursors are non-volatile solids while MITC itself is a highly volatile compound with a vapor pressure of 16 mmHg. Metam potassium and metam sodium are colorless when pure and may range from odorless to a fairly strong odor of amine or sulfur; dazomet has a white-yellow appearance and may be odorless or pungent and acrid to humans (NCBI 2015; Tomlin 2000). The compounds are stable when pure or in concentrated aqueous solutions. They become unstable when heated, diluted or exposed to sunlight and extreme pH conditions (Tomlin 2000). All compounds are broad-spectrum biocides and are listed for use as herbicides, fungicides, and nematicides.

**Table 1:** Physical and chemical properties of metam sodium, metam potassium, dazomet, and MITC.

|   | Compound  |   |  |   |
|---|---|---|--|---|
| <b>Chemical Structure</b>                                   |  |  |  |  |
| <b>Chemical Name</b>  | Metam sodium  | Metam potassium   | Dazomet  | Methyl isothiocyanate   |
| <b>IUPAC Name</b>   | sodium;N-methylcarbamodithioate   | potassium;N-methylcarbamodithioate  | 3,5-dimethyl-1,3,5-thiadiazinane-2-thione  | methylimino(sulfanylidene)methane   |

## 2.2 Environmental Persistence

MITC results from the breakdown of dazomet or either of the dithiocarbamate salts at the immediate site of application (DPR 2002). Additionally, the breakdown of any precursor compound depends on the environmental conditions present and the medium to which they are applied. Due to its high vapor pressure of 16.0 mmHg, MITC rapidly volatilizes upon the application of its parent compounds to soil. MITC is primarily degraded by gas phase photolysis (DPR 2002). The level of MITC in air is dependent upon two factors: the rate of breakdown by photodissociation, and the reactivity of the compound with available atmospheric oxidants (oxygen, ozone, and free radicals) (DPR 2002). Under laboratory conditions, MITC was observed by Geddes et al. (1995) to have half-lives ranging from 8.9 hours ( $\pm 2.4$ ) to 13.1 hours ( $\pm 2.4$ ).

The hydrolysis rate of MITC is low in water, but is significantly increased upon the addition of sediments similar to those found in bodies of water (DPR 2002). Hydrolysis half-lives of 15, 65, and 0.7 days were observed at pH 4, 7, and 10, respectively, at 25 °C in buffered aqueous solutions. Breakdown of MITC appeared to be optimal under a basic environment and most inhibited at neutral pH. The addition of sediment was observed to increase the rate of hydrolysis by 69% at 10 °C (Geddes et al. 1994). Due to the relatively low leaching and fast degradation of MITC when in the presence of water with sediments, the potential for groundwater contamination is low (Tomlin 2000).

In soil, MITC is primarily transported and transformed by volatilization and hydrolysis. Ranked in order of influence, the temperature, type, pH, and moisture content of a soil determine the rate of MITC loss (Ashley et al. 1963). As with most chemicals, warmer temperatures facilitate volatilization, while cold, wet conditions reduce volatilization rates (Van den Berg et al., 1999). Soils lower in organic content allow greater volatilization than soils high in organic content, such as peat (Gerstl et al. 1977; Ashley et al. 1963). Generally, MITC adsorption is low for soils, but increased levels of clay and organic matter can increase adsorption.

### **2.3 Regulation and Human Health**

Dazomet, metam potassium and metam sodium were first registered as pesticides in the US by the US EPA in 1967, 1973 and 1975, respectively (EPA 2008). Originally, dazomet and metam potassium were registered to control microbes and fungi in both commercial and industrial settings; in 1994, metam potassium's use was expanded to incorporate food and feed uses when used as a soil fumigant. Metam sodium was first registered as an agricultural pesticide and is now also registered for antimicrobial and industrial uses. Pesticides containing dazomet, metam sodium and metam potassium were first registered with California in December 1980, January 1981, and January 1982, respectively. They are currently approved for use in soil applications in California, with metam sodium also approved for use in sewage systems and wood protection.

In response to public complaints of illness and irritating odors near metam sodium-treated agricultural fields, air monitoring studies were conducted in 1993 and 1994 which determined that off-site concentrations of MITC exceeded concentrations known to cause eye irritation under certain application methods and weather conditions (DPR 2002). As a result, in 1994 DPR adopted regulations which designated metam sodium and MITC as restricted materials when labeled for the production of agricultural plant commodities (DPR 2002; Titles 3 and 26, California Code of Regulations §6400). Metam potassium and dazomet were also designated as restricted materials in 2001 by DPR (DPR 2002).

Restricted materials are defined by DPR as pesticides deemed to have a higher potential to cause harm to public health, farm workers, domestic animals, honeybees, the environment, wildlife, or other crops compared with other pesticides. Restricted materials may be purchased and used only by or under the supervision of a certified commercial or private applicator under a permit issued by the County Agricultural Commissioner (DPR 2008).

In May 2015, DPR updated the recommended conditions for field soil fumigation when using dazomet, metam potassium and sodium. The revised permit conditions were designed to mitigate health hazards associated with offsite movement of MITC following applications of metam sodium and metam potassium (DPR 2015b).

### **3 Pesticide Use Reporting**

The State of California requires the reporting of all registered agricultural pesticide applications. The collected use information is stored in the Pesticide Use Report (PUR) database. Agricultural use includes the application of pesticides to growing crops, agricultural fields, and most applications to forest trees and ornamental turf. PUR data includes the pesticide product used, the date of application, and the geographical coordinates of area treated. All agricultural uses of pesticides are reported to county agricultural commissioners who then report the data to DPR.

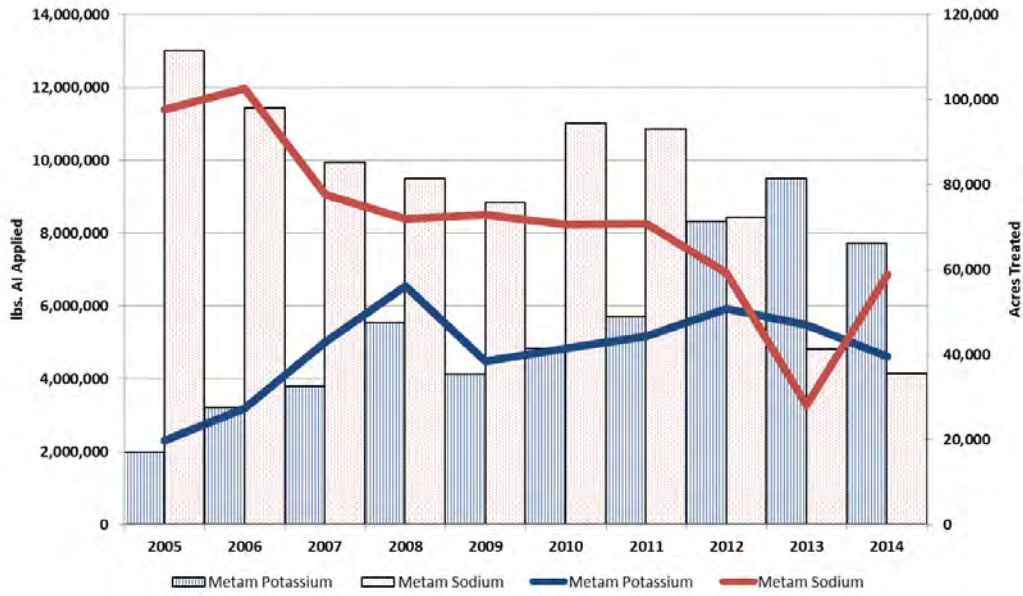

#### **3.1 Data Quality**

A total of 32, 21, and 9,126 records were queried from PUR database that were within five miles of the Salinas, Shafter, and Ripon AMN sites, respectively. Once queried, the data were then subjected to a quality assurance check by comparing the application amount to the acres treated to calculate the application rate. Any entries with calculated rates greater than 10% the established label rate were flagged for review and omitted from further analysis. One record was flagged and omitted for the 2011 – 2014 MITC dataset for Salinas due to an atypical application rate.

#### **3.2 Use Profile in California**

Metam sodium and metam potassium have both been included in DPR's list of top 100 pesticides used (by weight) statewide since 2001, signifying the compounds' importance and utility in agriculture and industry (DPR 2015c). Metam sodium and metam potassium are normally sold as liquid concentrates to be applied directly to the soil for chemigation by sprinkler, flood and drip irrigation, and by shank injection; rotary tiller or power mulcher applications are also possible. Dazomet, sold as products with a dry, granular formulation, is applied directly to soil by scoops, shakers, shanks, drop-type fertilizer spreaders, or other suitable equipment for deploying granular solids.

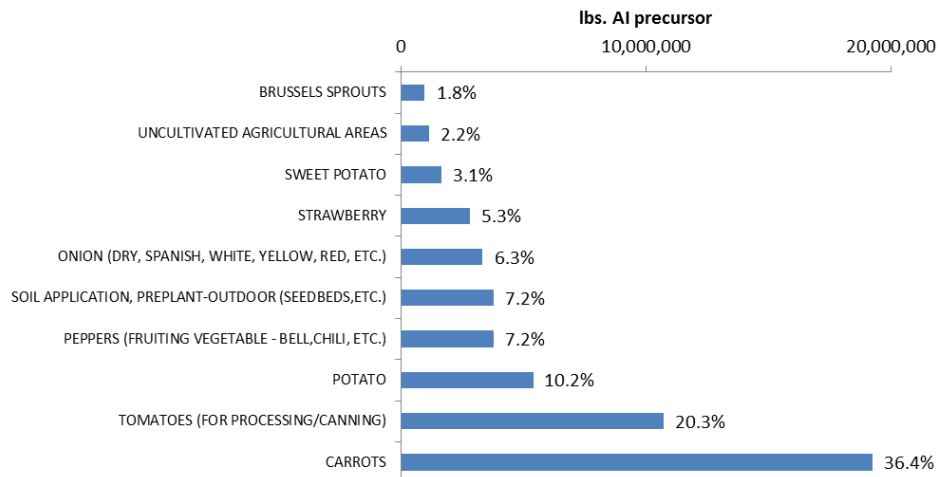

The broad spectrum biocidal activity of MITC makes the precursors highly desired for pre-planting soil fumigation to control bacterial, fungal, plant and insect pests. A review of the past 10 years shows that the historical usage of MITC, in terms of both pounds applied and area treated, has varied (Figure 1). However, due to the phase out of the ozone-depleting fumigant methyl bromide, the use of MITC as an alternative fumigant may become more common in the future.

**Figure 1:** Statewide use of metam potassium and metam sodium (bars) from 2005 – 2014, shown alongside the acreage of land treated (lines) for each year. Data obtained from queries of the PUR database in November 2015.

The use patterns of MITC-precursors in California can be largely assigned to soil-applied, agricultural uses for food crops, like onion and potatoes. Querying of the PUR database between 2011 – 2014 determined that only 1% (by weight) of MITC precursors used was for non-agricultural purposes in California, such as wood treatment. Figure 2 shows that of the agricultural MITC applications in California between 2011 – 2014, over half were for carrot and tomato (for processing/canning) crops alone.

#### Use of MITC Precursors by Crop 2011 - 2014

**Figure 2:** Percent of 2011 – 2014 statewide MITC applications by crop. Data obtained from queries of the PUR database in November 2015.

## **4 Air Monitoring Network**

In 2011, DPR established the AMN to sample ambient air concentrations of 37 compounds (32 pesticides and 5 breakdown products) in three rural agricultural communities in California: Ripon, Salinas, and Shafter. The communities were chosen based upon pesticide use and demographic data among other factors described elsewhere (DPR 2011). During the course of the AMN, personnel collected 24-hour air samples on randomly selected days once per week in each of the three communities.

### **4.1 Air Monitoring Network Methods**

To measure for MITC, anasorb and coconut charcoal sorbent tubes were used with personal sample pumps operating at 1,500 mL/min for 24 hours (DPR 2011). Air flow was measured at the beginning and end of each sample period. The weekly starting day varied through the week and was randomly selected when possible. All samples were immediately placed upon dry ice once the sampling period ended and were stored at  $-20^{\circ}\text{C}$  until analyzed.

In a partnership with the California Department of Food and Agriculture (CDFA), the samples were analyzed by CDFA's Center for Analytical Chemistry laboratory personnel and the resulting mass of MITC determined (DPR 2011). The mass of MITC was then divided by the volume of air sampled to determine the average ambient concentration of MITC measured during the sampling period. Samples with concentrations measured below the Method Detection Limit (MDL  $5.6\text{ ng/m}^3$ ), defined as the lowest concentration of analyte that a particular analytical method can reliably detect (qualitative), were recorded as non-detects (NDs). For the purposes of analysis, NDs used adjusted values as one half of the MDL ( $2.8\text{ ng/m}^3$ ) when estimating exposure values. Samples with positive detections, but at levels below the Limit of Quantification (LOQ,  $11.6\text{ ng/m}^3$ ), defined as the lowest concentration of analyte that the method can reliably quantify (quantitative), were reported as trace detections. For the purposes of analysis, trace detections were substituted with the average of the sum of the quantitation limit and method detection limit ( $14.3\text{ ng/m}^3$ ).

### **4.2 Air Monitoring Network Results**

Of the three sites in the AMN, the most number of detections and quantified detections occurred in Shafter, followed by Ripon. The peak acute exposure measurement,  $930.4\text{ ng/m}^3$ , also occurred in Shafter; Ripon had the second highest 24-hour measurement of  $852.2\text{ ng/m}^3$ . These peak detections represent only 1.4 and 1.3% of the acute screening level in Shafter and Ripon, respectively.

Salinas had the fewest detections overall and the lowest observed peak 24-hour detection of  $233.8\text{ ng/m}^3$ . These trends continued for chronic exposure (4-week), with Shafter, Ripon, and Salinas ranked from highest to lowest. Table 2 summarizes the AMN results from February 1, 2011, to December 31, 2014.

**Table 2:** Summary of AMN network results including information on the highest recorded concentration at the acute exposure (24 hour, 66,000 ng/m<sup>3</sup>) and chronic exposure (1-year, 300 ng/m<sup>3</sup>) levels (Tuli et al. 2015; Vidrio et al. 2014; Vidrio et al. 2013a/b.).

|   | Salinas | Shafter | Ripon |
|---|---------|---------|-------|
| <b>Number of possible detections</b>                    | 204     | 204     | 205   |
| <b>Total number of detections</b>                       | 22      | 100     | 54    |
| <b>Number of quantified detections</b>                  | 17      | 90      | 51    |
| <b>% of possible detections</b>                         | 10.8    | 49.0    | 26.3  |
| <b>% of quantifiable detections</b>                     | 8.3     | 44.1    | 24.9  |
| <b>Highest acute concentration (ng/m<sup>3</sup>)</b>   | 233.8   | 930.4   | 852.2 |
| <b>% of screening</b>                                   | 0.4     | 1.4     | 1.3   |
| <b>Highest chronic concentration (ng/m<sup>3</sup>)</b> | 11.7    | 72.9    | 37.2  |
| <b>% of screening</b>                                   | 3.9     | 24.3    | 12.4  |

## 5 Meteorological Data

Weather information was taken from meteorological stations operated by the Department of Water Resources, as part of the California Irrigation Management System (CIMIS). The stations form a network throughout agricultural areas in California which monitor weather data at hourly intervals for precipitation, air temperature, and wind speed and direction, amongst others. For this analysis, only wind speed and direction from February 1, 2011, to December 31, 2014, were taken into consideration.

The nearest meteorological station to the AMN sampling site in Salinas was CIMIS station #116 and for Ripon it was station #71. For the community of Shafter, CIMIS station #5 was the closest to the AMN sampling site, but this station's collected data had a 2-year gap in wind direction. Instead, the second closest station, #138 in Famoso, was used as a source of weather data. All stations were in areas where the surrounding terrain is flat.

The weather data were then used to create wind rose graphs to show the wind direction and speed, as a percentage of time, for the areas near the sampling stations. The wind roses display the frequency of winds blowing from a cardinal direction over a given period of time, and the length of each spoke on the rose represents the percentage of time wind blew from that particular direction.

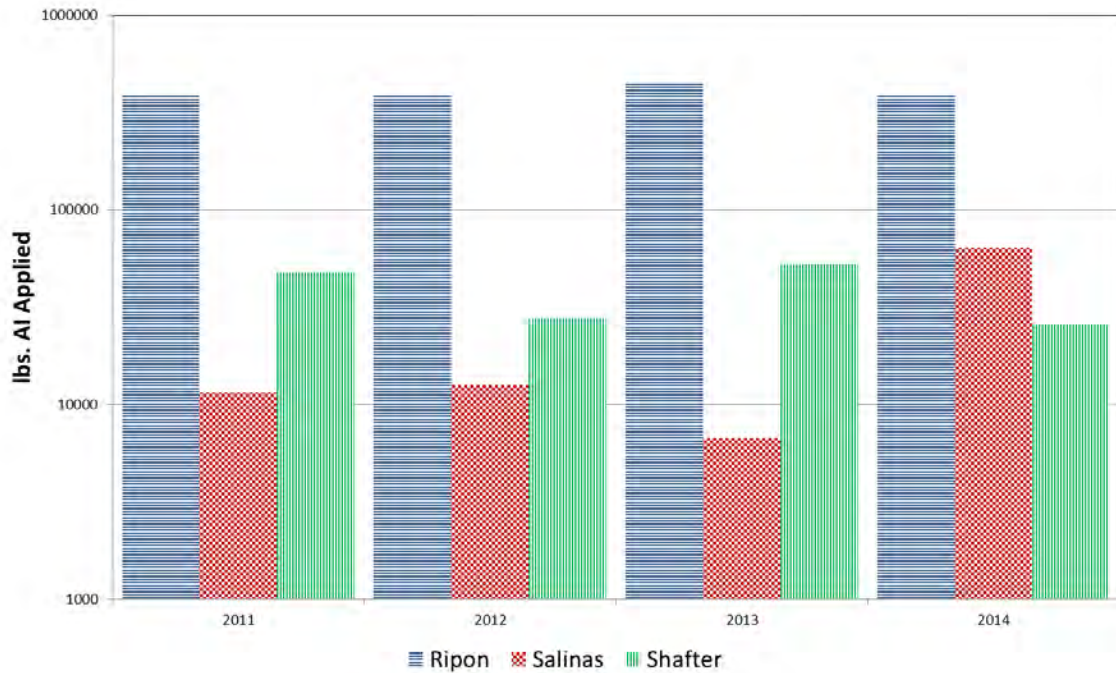

## 6 Use Profiles near Air Monitoring Network Sites

The use profiles for the sites monitored in the AMN varied over time (Figure 3). Data are depicted logarithmically due to the large differential between the total amounts of active ingredient applied in each area. MITC use by weight was relatively constant in Ripon, deviating only up to ~15% from year-to-year. Additionally, MITC use was 2 to 10 times higher in Ripon compared to the other communities studied in the AMN.

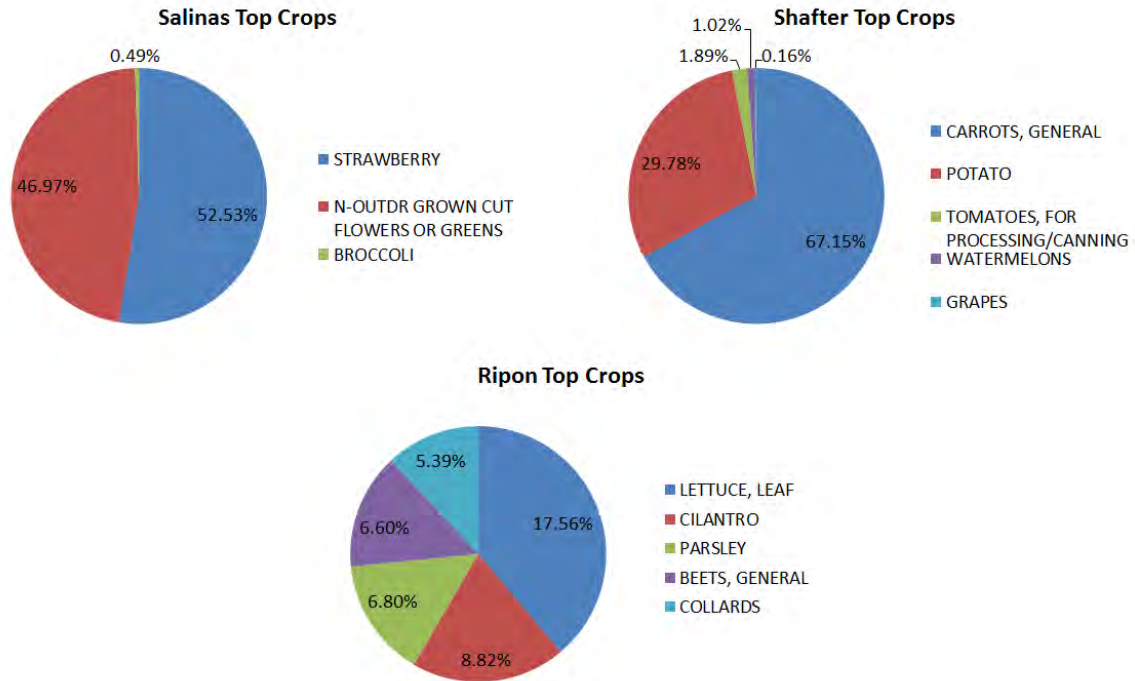

In Salinas, MITC use dropped to nearly half in 2013 compared to the previous year, but increased almost 10-fold from 2013 to 2014, demonstrating variable use over time. The use profile in Shafter showed less variability compared with Salinas. In Shafter, the greatest decrease in use occurred from 2012 to 2013 while the greatest increase occurred the next year in 2013 to 2014.

Figure 4 summarizes MITC use by top crops for each site in the AMN from 2011 to 2014. Top crops vary for all sites with strawberry, carrots, and lettuce being the top crops for Salinas, Shafter, and Ripon, respectively.

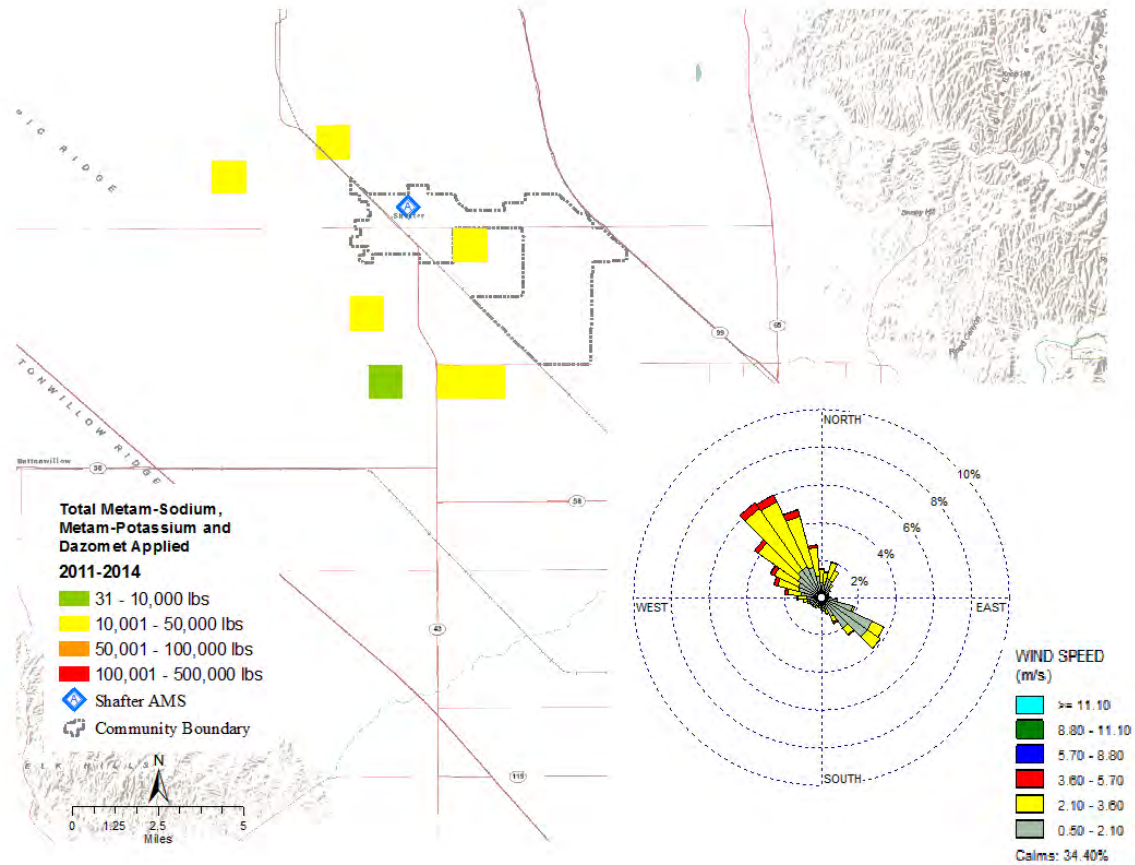

**Figure 3:** MITC use profile from February 1, 2011 to December 31, 2014, for all sites in the AMN. Data obtained from queries of the PUR database in November 2015.

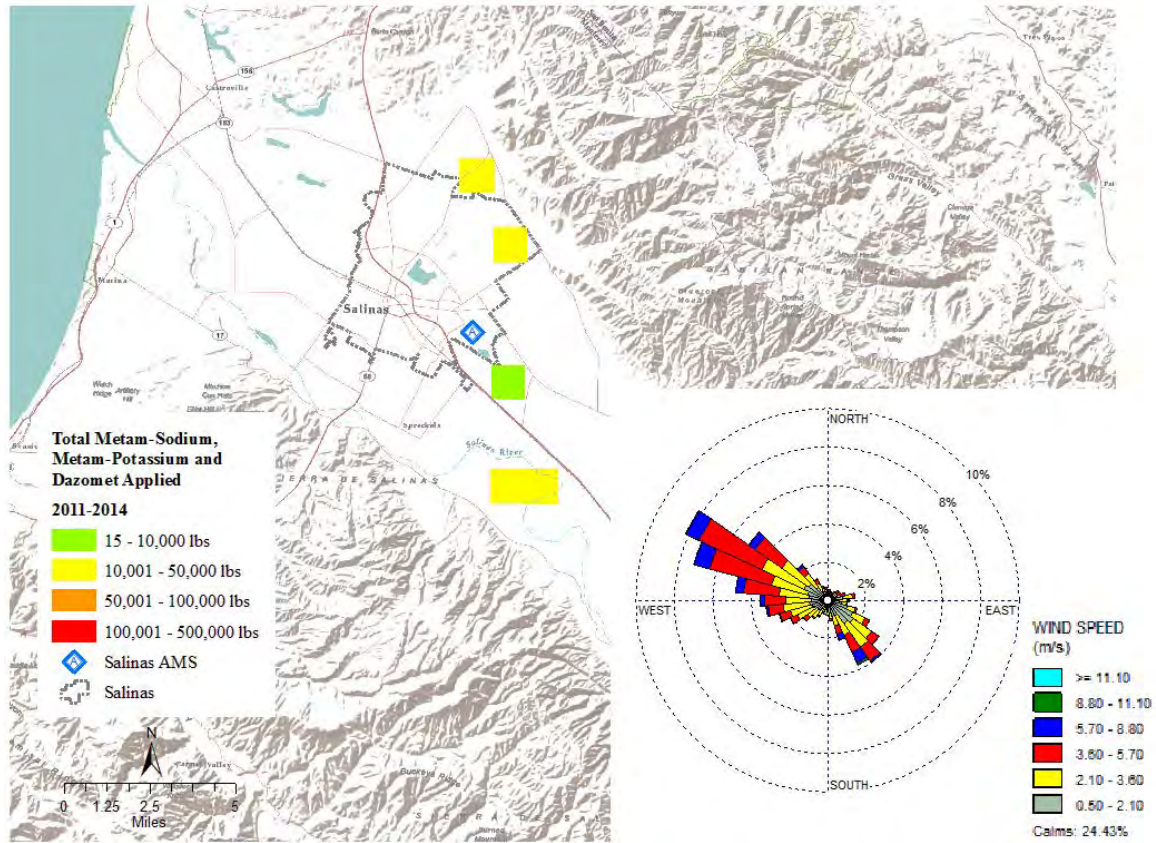

**Figure 4:** MITC use by crop from February 1, 2011, to December 31, 2014, for all sites in the AMN. Data obtained from queries of the PUR database in November 2015.

The geographic distribution of MITC-precursor applications made within 5 miles of the three AMN sites was also examined. The cumulative use of MITC-precursor as pounds of active ingredient from February 2011 through December 2014 for each square mile Public Land Survey System (PLSS) section was summed and entered into ArcMap® 10.3.1 graphical software.

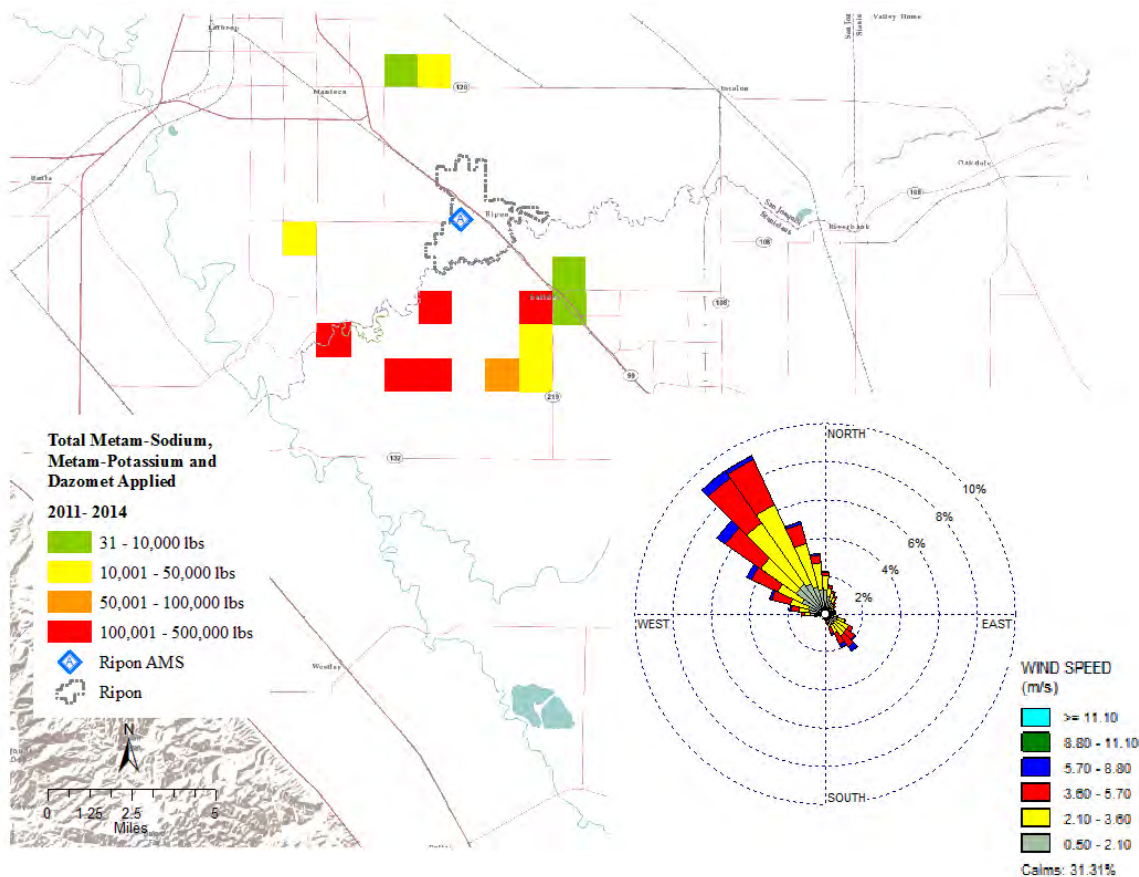

The cumulative use of MITC-precursor as an active ingredient from February 2011 through December 2014 for each of the communities along with the wind roses is shown below in Figures 5 – 7. The community boundary as defined by the US Census in 2010 for Salinas and Ripon was used. The 2000 Census boundary was used for Shafter since the updated 2010 boundary included an expansion in the community boundary in anticipation of future development; as of the date of this report, the development has not yet occurred (LSA 2005).

**Figure 5:** Cumulative applications of MITC-producing precursors in a 5-mile radius centered on the Shafter AMN sampling station along with wind roses showing percentage of time for each direction the wind is coming from and wind speed, February 1, 2011 - December 31, 2014.

**Figure 6:** Cumulative applications of MITC-producing precursors in a 5-mile radius centered on the Salinas AMN sampling station along with wind roses showing percentage of time for each direction the wind is coming from and wind speed, February 1, 2011 - December 31, 2014.

**Figure 7:** Cumulative applications of MITC-producing precursors in a 5-mile radius centered on the Ripon AMN sampling station along with wind roses showing percentage of time for each direction the wind is coming from and wind speed, February 1, 2011 - December 31, 2014.

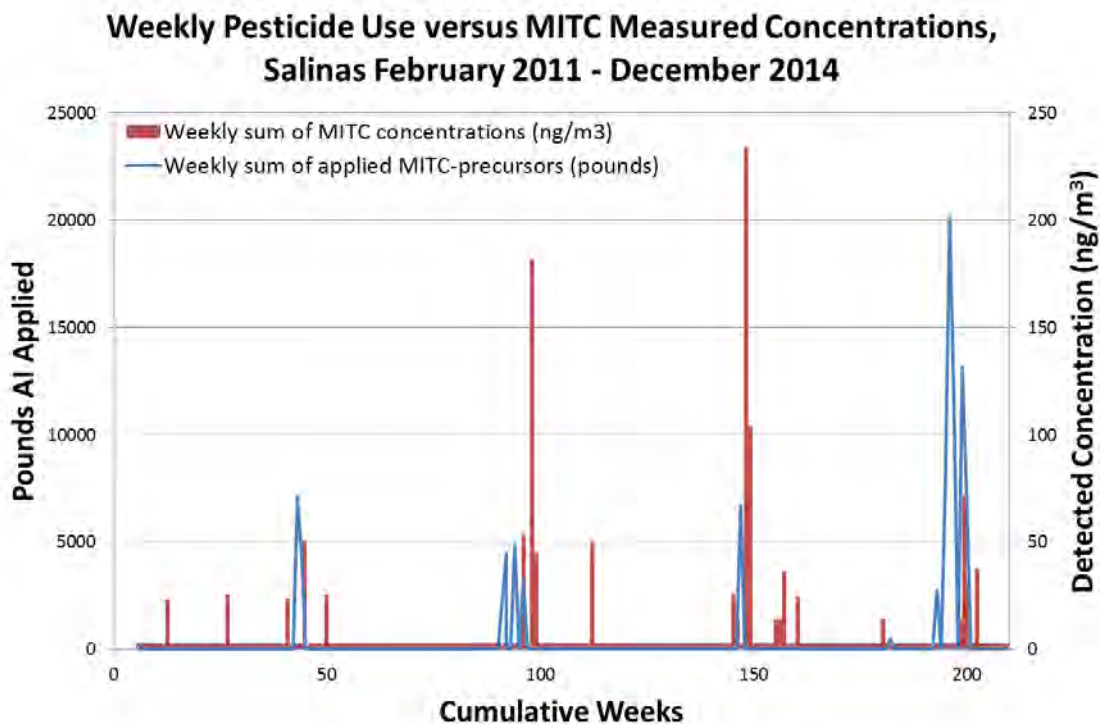

## 7 Comparison of Air Monitoring Network Measured Concentrations to Pesticide Use Reports

The applications of MITC-precursors up to 5 miles from the AMN sampling sites along with detected concentrations of MITC from February 1, 2011, to December 31, 2014, are displayed on Figures 8-10. As shown in Figure 8, measured concentrations of MITC may align with reported applications as a function of time for Salinas during the weeks of October and November in 2012 to 2014.

The largest detected concentration of  $233.8 \text{ ng/m}^3$  (week 148) occurred four days after an application of 6,724 pounds of MITC to a 25-acre field approximately 4.75 miles southeast of the AMN sampling site. The detection and application on the 199<sup>th</sup> and 200<sup>th</sup> week of the study also seemed to correlate. These applications occurred approximately 4.5 to 4.75 miles to the south and southeast with a total of 24,406 pounds applied on week 199 and 13,448 pounds the next week.

In Salinas, there are occurrences where ambient concentrations of MITC were measured as quantifiable but without reported applications occurring within 5 miles. This was also observed for the AMN site at Shafter (Figure 10). Multiple detections do occur during

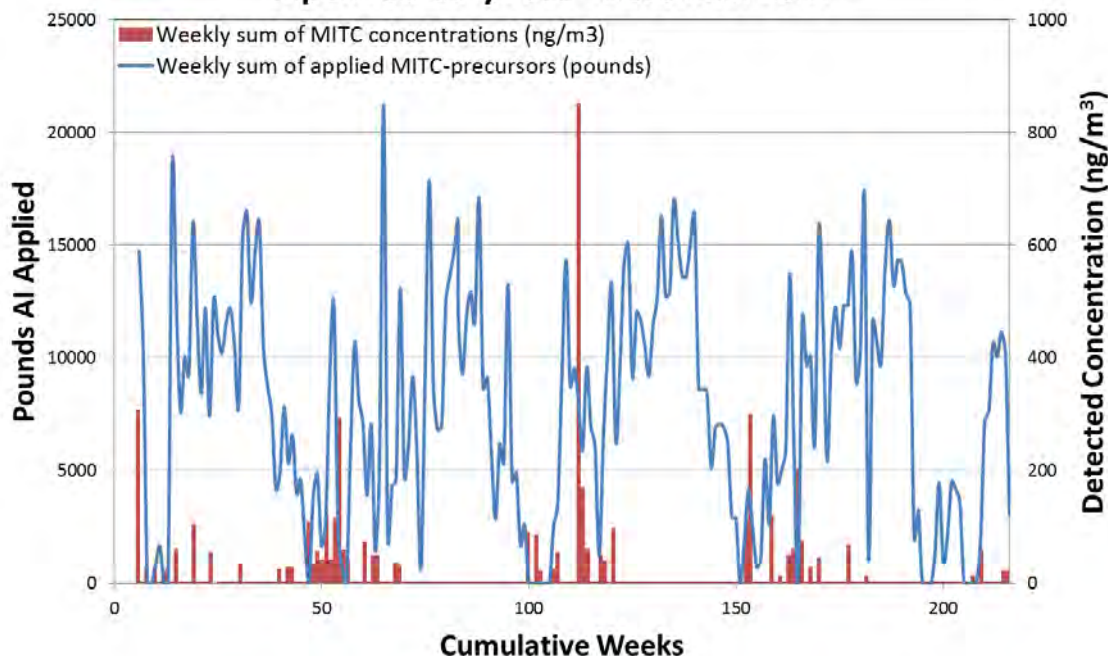

period of high use of MITC (approximately June – August and November – February), but there are many detections without reported applications within weeks or months from the time of detection.

**Figure 8:** MITC applications compared to AMN monitoring data in a 5-mile radius surrounding the Salinas sampling site between 2011 – 2014. Data are plotted by week.

In Ripon, reported applications of MITC essentially spanned the entire four-year period (Figure 9). However, peak applications do not appear to correspond to high levels of MITC detections. The week with maximum reported MITC applications occurred on week 65 (3/25/2012 – 3/31/2012) with a total of 21,211 pounds of MITC applied coming from 57 individual applications. Although week 65 contained the highest use total for Ripon, it did not lead to the highest MITC concentration detected at this site (Figure 9). Instead, the highest MITC concentration of 852.2 ng/m<sup>3</sup> was detected on January 23, 2013 (week 108) which coincided with a reported weekly total use of 6,116 pounds of MITC applied. This total use was comprised of various daily applications on mostly small 1-acre plots up to the date of detection. However, these applications rank in the bottom half of total MITC applied when totaled by week throughout the study.

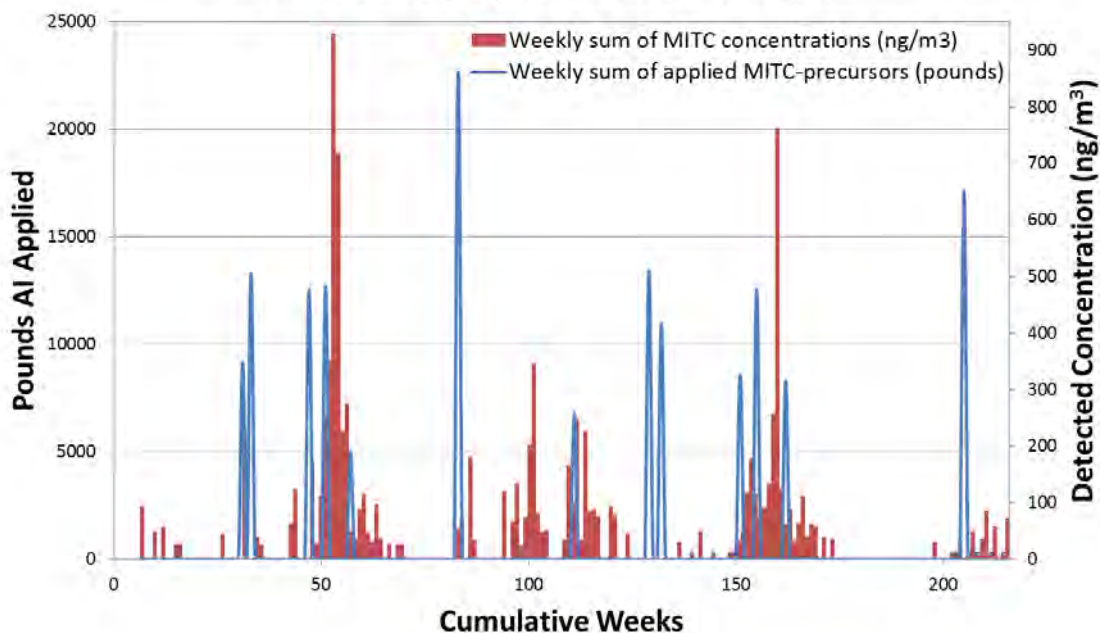

### Weekly Pesticide Use versus MITC Measured Concentrations, Ripon February 2011 - December 2014

**Figure 9:** MITC applications compared to AMN monitoring data in a 5-mile radius surrounding the Ripon sampling site between 2011 – 2014. Data are plotted by week.

In Shafter, peak detections did not appear to correspond to time points of high application amounts. The highest detected concentration (930.4 ng/m<sup>3</sup>) occurred on December 12, 2011, and was part of a period of consecutive positive detections at Shafter, from November 16, 2011 to March 7, 2012. Figure 10 displays MITC applications along with AMN measured concentrations of MITC in a five mile radius surrounding the Shafter sampling location.

### Weekly Pesticide Use versus MITC Measured Concentrations, Shafter February 2011 - December 2014

**Figure 10:** MITC applications compared to AMN monitoring data in a 5- mile radius surrounding the Shafter sampling site between 2011 – 2014. Data are plotted by week.

## 8 Linear Regression Analyses

The potential statistical correlation between AMN measured concentrations and reported use data at various distances (1, 2, 3, 4, and 5 miles) from the Shafter AMN site was evaluated by linear regression. Linear regression was attempted for all AMN sites, but only the linear regression analysis for the Shafter AMN site is reported in this section due to weak statistical relationships between MITC use and detections for the other sampling locations (see Appendix for regression plots for Salinas and Ripon AMN locations).

### 8.1 Methods

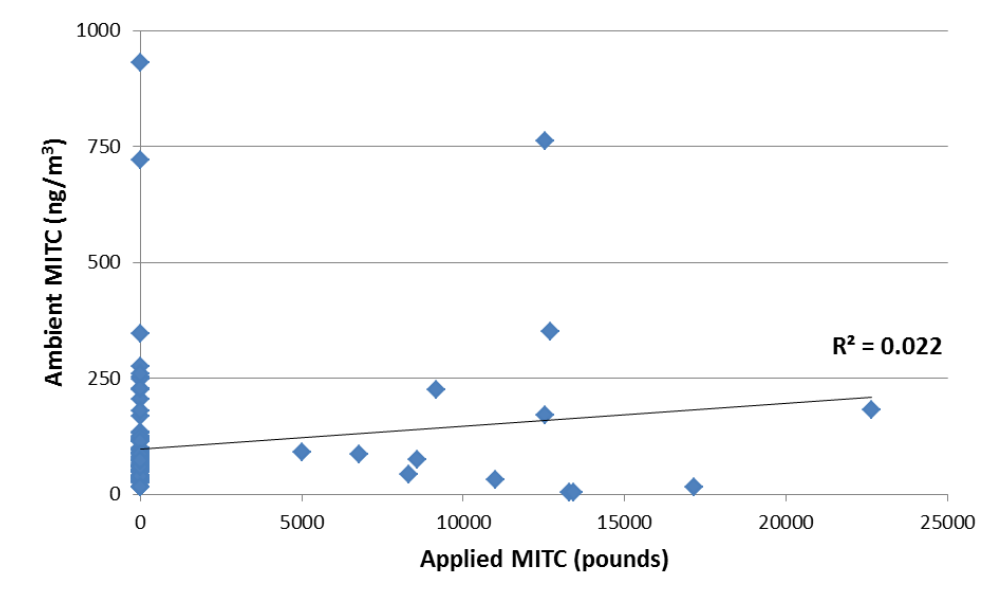

Prior to the data analysis, yearly subsets of AMN data were omitted from regression modeling if more than 90% of possible detections for a year were non-detections. With this restriction, only the 2012 dataset for Salinas was excluded since 94% of its possible detections were determined to be non-detections.

For each distance (1, 2, 3, 4, and 5 miles) from each AMN station, the same approach and statistical methods were utilized. PUR results were reported by week, beginning January 2011, and matched to the corresponding sampling week in the AMN. Multiple PUR records for any given week were summed and ultimately defined as pounds of MITC, or active ingredient (AI). The application and detection of MITC was then plotted as a function of time (weeks) and then observed if a relationship existed between the variables.

## 8.2 Results

Regression analysis of MITC use and detection at all sites in the AMN during 2011 – 2014 gave an overall poor fit with an application radius of 5 miles. The model fit was most linear for the Shafter dataset, with an  $R^2$  value of 0.022 (Figure 11).  $R^2$  coefficient values ranged from 0.001 to 0.022 for all year datasets when PUR data were queried at a distance up to 5 miles from the sampling stations (Figure 11 and Appendix). Subsequent analysis with reduced distances (1, 2, 3, and 4 miles) did not improve correlation.

**Figure 11:** Regression plots for the Shafter AMN site 2011 – 2014.

The low frequency of detections during periods of MITC use and the occurrence of detections during no MITC use hindered attempts to determine a relationship between MITC applications and detections. Table 3 summarizes the total number of weeks of MITC use and weeks without use compared to the total number of weeks of either MITC detections or no detections for the three AMN sites between 2011 through 2014.

The 5-mile area surrounding the Ripon sampling site had the highest use of MITC by frequency and weight in the AMN. During weeks in which MITC use was reported in Ripon, ambient MITC detections occurred only 25% of the time. Conversely, MITC was detected 40% of the time during weeks with no reported MITC use within a 5-mile area surrounding Ripon. The detection of MITC during periods of no reported use could have resulted from delayed emissions of MITC from soil treated during weeks prior to monitoring.

Both 5-mile areas around the Salinas and Shafter AMN sites had 2 to 10 times less use of MITC by weight compared to Ripon. Approximately 23% of the samples collected in Salinas during weeks of MITC use resulted in positive detections, whereas 69% of the samples collected in Shafter during weeks of MITC use resulted in positive detections. Comparatively, positive detections accounted for 10% and 46% of the weeks with no use

in Salinas and Shafter, respectively. The average wind speed in the Shafter area was just over half the average wind speed in Salinas (Table 3) which may have influenced the AMN's ability to detect ambient MITC, even when detections may be due to delayed soil emissions from applications made outside of the 5-mile radius. Additionally, low wind speeds can lead to higher ambient air concentrations of fumigants due to less mixing and reduced emission rates.

**Table 3.** Comparison of the number of weeks from 2011 – 2015 with use or no use and detections.

|                           | Ripon           |               | Salinas         |               | Shafter         |               |
|---------------------------|-----------------|---------------|-----------------|---------------|-----------------|---------------|
|                           | With Detections | No Detections | With Detections | No Detections | With Detections | No Detections |
| <b>Weeks With Use</b>     | 46              | 138           | 3               | 10            | 9               | 4             |
| <b>Weeks With No Use</b>  | 8               | 12            | 19              | 172           | 88              | 103           |
| <b>Average Wind Speed</b> | 2.00 m/s        |               | 2.38 m/s        |               | 1.02 m/s        |               |

## 9 Conclusions

All three AMN sites have unique detection-use profiles in regards to the agricultural use of MITC-precursors. Data from the three sites show measured ambient MITC concentrations were not statistically correlated to the weekly use of MITC-precursors applied to agricultural fields within 5 miles of the AMN sampling sites during 2011 to 2014. Detections of MITC during weeks without the use of MITC-precursors, particularly in Salinas and Shafter which had longer periods without use, indicates that some number of detections may have occurred from MITC applications made further than 5 miles from the sampling sites. The data also suggests that wind speed and direction may have influenced the quantity of positive MITC detections.

As a study designed to estimate potential long-term exposure, the AMN has limitations in determining a statistical relationship to individual applications and estimating 24-hour ambient concentrations of pesticides since sampling occurs one day a week. The AMN was intended to determine trends in long-term exposure, not daily fluctuations of individual pesticides. In addition, methods of fumigant application which are designed to mitigate off-site movement of MITC and local weather at the time of application may all affect detection ability.
